Introduction

- Introduces a DNN interpretation method called "Agglomerative Contextual Decomposition(ACD)"
- hierarchical interpretations to explain DNN predictions
- hierarchical clustering of the input features, with a contribution score for each cluster to the final prediction

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

ACD Overview

- Hierarchical clustering of features given the prediction from a DNN
- hierarchy optimized to indetify clusters of features identified by a DNN that are predictive

CD+Hierarchical Agglomerative Clustering

Method: Contextual Decomposition for General DNNs

Generalize CD for general DNNs

• A general DNN f(x) = Softmax(g(x))

$$f(x) = Softmax(g_L(g_{L-1}...(g_1(x))))$$

Given a group of features S {x_j} j ∈ S, decompose g(x) = β(x) + γ(x)

•
$$g^{CD}(x) = (\beta(x), \gamma(x))$$

• $\beta(x)$ is contribution from S, and $\gamma(x)$ is contribution from rest

Method: Contextual Decomposition for General DNNs

- To get this final value, recompute decomposition for every layer
- For every layer *i*, $\beta_i(x) + \gamma_i(x) = g_i(x)$
- By compositing all these decompositions

$$f(x) = Softmax(g_L^{CD}(g_{L-1}^{CD}...(g_1^{CD}(x))))$$
(2)

 Recomputing these for different types of layers: Conv, Pool, Relu

Method: Contextual Decomposition for General DNNs Conv Layer

$$\beta_{i} = W\beta_{i-1} + \frac{|W\beta_{i-1}|}{|W\beta_{i-1}| + |W\gamma_{i-1}|} \cdot b$$
(3)

$$\gamma_i = W\gamma_{i-1} + \frac{|W\gamma_{i-1}|}{|W\beta_{i-1}| + |W\gamma_{i-1}|} \cdot b \tag{4}$$

MaxPool Layer

$$\max_{idxs} = \underset{idxs}{\operatorname{argmax}} \left[\max_{i=1} \left(\beta_{i-1} + \gamma_{i-1}; idxs \right) \right] \quad (5)$$

$$\beta_i = \beta_{i-1}[\max_{i \in S}] \tag{6}$$

$$\gamma_i = \gamma_{i-1}[\max_{i \in \mathcal{S}}] \tag{7}$$

ReLU Layer

$$\beta_i = \mathsf{ReLU}(\beta_{i-1}) \tag{8}$$

$$\gamma_i = \mathsf{ReLU}(\beta_{i-1} + \gamma_{i-1}) - \mathsf{ReLU}(\beta_{i-1})$$
(9)

• Gives importance scores β_i for all feature groups

Method: Agglomerative Contextual Decomposition

Algorithm 1 Agglomeration algorithm.	
ACD(Example x, model, hyperparameter k, function CD(x, blob; mode	4))
# initialize	
tree = Tree()	# tree to output
scoresQueue = PriorityQueue()	# scores, sorted by importance
for feature in x :	
scoresQueue.push(feature, priority=CD(x, feature; model))	
# iteratively build up tree	
while scoresQueue is not empty :	
selectedGroups = scoresQueue.popTopKPercentile(k)	# pop off top k elements
tree.add(selectedGroups)	# Add top k elements to the tree
# generate new groups of features based on current groups and ac	ld them to the queue
for selectedGroup in selectedGroups :	
candidateGroups = getCandidateGroups(selectedGroup)	
for candidateGroup in candidateGroups :	
scoresQueue.add(candidateGroup, priority=CD(x, candid	ateGroup;model)-CD(x,selectedGroup;
model))	
return tree

Results: Dataset Bias

Orange area very large : both skates and puck to classify as puck

Quantitative Results: Robust to Adversarial Perturbation

- Compute two ACDs: one for original image and the other for perturbed image
- Compute ranking of each pixel in each ACD based on when it was added into the hierarchy
- Compute correlation between adversarial vs original image

Attack Type	ACD	Agglomerative Occlusion
Saliency (Papernot et al., 2016)	0.762	0.259
Gradient attack	0.662	0.196
FGSM (Goodfellow et al., 2014)	0.590	0.131
Boundary (Brendel et al., 2017)	0.684	0.155
DeepFool (Moosavi Dezfooli et al., 2016)	0.694	0.202

Table 2: Correlation between pixel ranks for different adversarial attacks. ACD achieves consistently high correlation across different attack types, indicating that ACD hierarchies are largely robust to adversarial attacks. Using occlusion in place of CD produces substantially less stable hierarchies.

Quantitative Results: How much trust in the model: human study

Figure 4: Results for human studies. A. Binary accuracy for whether a subject correctly selected the more accurate model using different interpretation techniques **B**. Average rank (from 1 to 4) of how much different interpretation techniques helped a subject to trust a model, higher ranks are better.
